World population growth, water crisis, and climate change are the challenges facing humanity. But on the other hand, economic crises are affecting the world's agriculture. If the governments of the world do not think about the basic management of agriculture, a serious crisis will arise in the future in the field of food. The large class gap between the farmer class and many other classes of society has caused this class to face many problems. The high cost of agricultural products, if not accompanied by government subsidies, will severely reduce the purchasing power of society, but the policy of allocating subsidies to manufactured products is not beneficial to farmers because they will still sell their products cheaply. The solution to such a crisis in the not-too-distant future is to strengthen the direct supply systems of agricultural products in the form of agricultural cooperatives. This system will contribute to the profit of the farmers in the entire supply cycle of agricultural products. It is only in this way that agriculture will bear the trouble of producing crops.

The research of scientists in the field of agriculture should be focused on making production easier and reducing its cost. To increase the shelf life of the products and at the same time to increase the quality of the supplied products. Besides all these valuable qualities, the philanthropic researcher also cares about the health of future generations, so producing a healthy product is a priority for him. Researchers, farmers, and businessmen in the agricultural sector will be able to save the future of agriculture in the world only if they act together and united, and the mission of agricultural researchers in this field is more visible than ever.
