### Abstract

This research deals with the how virus evolve from single cell and from environment involve the synthesis of the virus formation and new virus formation.

**Keywords:** DNA; Mutation; DNA Backward Rolling; DNA Forward Rolling

Virus evolution from the single cell

Virus form from the three types

Huge mutation in the single eukaryotic or prokaryotic cell [1]

- Misense mutation in huge amount in the DNA processing and RNA synthesis Leading to the formation of the obligatory Parasite virus [2].
- Mutation in the huge amount in the energy production in the single cell leading to the single cell deprivation leading to the formation of the obligatory parasite virus [3].
- Acient remains of DNA with accumulated mutation in the single cell can lead to the formation of the virus in the inactive formation [4].

Oncogenic virus formation [5].

In this formation oncogenes are activated along with deactivation or missense Mutation of the energy pathway leading to the formation of cancer-Causing virus. (Perfect example of the combination of DNA forward rolling and DNA Backward rolling) [6].

### Discussion

In this we researched about the how virus is formed and their method.

### Conclusion

Viruses can develop from huge amount of messenger mutation of the single cell organism and the energy pathway mutation and its partial deactivation and from primitive single Cell.
