Abstract

Purpose: Non-tuberculous *Mycobacteria* (NTM) infections are often misdiagnosed as tuberculosis due to the similar clinical and radiological presentations. NTM infections can be differentiated from tuberculosis only through species identification. Here we performed a species-level identification of NTM from sputum samples using ITS sequencing of the 16S-23S rRNA gene.

Materials and Methods: Twenty-one immunochromatographic assay negative isolates from smear-positive patients were collected and evaluated. The isolates were then subjected to mycolic acid extraction for HPLC, DNA isolation for line probe assay (LPA), *hsp65* and 16S-23S rRNA gene ITS sequencing.

Results: After evaluating all the diagnostic modalities for NTM, it was observed that the *Mycobacterium intracellulare* was the predominant slow-growing NTM (9/20, 45%), while *Mycobacterium abscessus* (subsp. *bolletii*) was the dominant rapid grower (5/20, 25%). One isolate, which could not be identified either by LPA or by HPLC, was detected as *Nocardia cyriacigeorgica*, by sequencing a non mycobacterial species predominantly found in pulmonary infection. The results of HPLC and LPA were 100% concordant. One isolate was identified as *M. abscessus* by sequencing, but HPLC and LPA detected it as *Mycobacterium chelonae*.

Conclusion: NTM should be considered as the key pathogen in immunocompromised patients and in patients with manifestations similar to tuberculosis. In such cases, species identification is critical for initiation of appropriate therapy. The 16S-23S rRNA gene ITS sequencing method is a rapid and accurate technique for NTM species identification up to subspecies.

Keywords: Non-tuberculous *Mycobacteria*; Internal Transcribed Spacer Sequencing; Line Probe Assay; HPLC

Key Messages

Present study helps in understating the NTM infections which are often misdiagnosed and incorrectly treated as tuberculosis due to the similar clinical and radiological presentations. In this study, we performed species identification of NTM using ITS sequencing of the 16S-23S rRNA gene and compared the results to those obtained using HPLC and line probe assay. Our findings indicate that the use of ITS (16S-23S rDNA ITS sequences) region sequencing is a rapid and reliable way of NTM species identification.

Introduction

Non-tuberculous *Mycobacteria* (NTM) are being increasingly recognized as the cause of chronic pulmonary and extra pulmonary disease. Among pulmonary tuberculosis patients who do not respond to anti-tuberculosis therapy, a high index of suspicion should be maintained for NTM as an etiological agent, and appropriate testing should be conducted to isolate them. At present, more than 60 types of NTM species that are pathogenic to humans have been

identified [1]. Their prevalence is especially high in immunocompromised hosts like PLHIV and organ transplant recipients, and early diagnosis and treatment is essential to prevent disease progression and further complications. The diseases caused by NTM present similar to tuberculosis, which often results in them being misdiagnosed as tuberculosis. Moreover, techniques for the identification of NTM are available only at select centres. Both these factors contribute to poor understanding of the epidemiology and disease burden of NTM. Traditional methods have relied on evaluation of the growth rate, pigment production, and colony morphology for preliminary identifications of NTM; however, rapid and accurate species identification is crucial to initiate appropriate therapy and to distinguish pathogenic species from contaminants [2].

The automated liquid culture system (MGIT 960) with commercial molecular techniques such as probe hybridization assay [GenoType Mycobacterium CM/AS (HAIN Life science, Germany)] can accurately identify species, yielding results within weeks [3]. High Performance Liquid Chromatography (HPLC) relies on an organism's mycolic acid (MA) content (fatty acids found in the cell walls of *Mycobacteria*) and is highly species specific; however, it is highly labour intensive and takes months to obtain the results [4]. Hence, there is a need for the development of a clinically useful and cost effective, rapid and accurate diagnostic test for species identification of NTM. The 16S-23S rRNA gene internal transcribed spacer (ITS) sequencing technique is highly specific for identifying most *Mycobacterial* species [5]. Although, there are other genes such as *hsp65*, *rpoB* and 16s rRNA genes were also used in various studies done worldwide [6-8]. In this observational study, we performed NTM species identification by ITS sequencing of 16S-23S rRNA gene region and compared the results of those obtained using probe hybridization assay [Geno Type Mycobacterium CM/AS (HAIN Lifescience, Germany)] and HPLC. We have also performed the *hsp65* gene sequencing as well to give more strength to NTM speciation experiments.

Materials and Methods

Ethical statement

The study was approved by institutional ethics committee and written informed consent was obtained from all the study participants.

Subject recruitment and initial processing

A total of 1619 sputum smear-positive samples [male; 1104 (68%), female; 515 (32%) with mean age of 35 ± 14.5 years] were received at Intermediate Reference Laboratory of the Department of Medicine at AIIMS, New Delhi between September 2013 and January 2016. All the patients were diagnosed with tuberculosis

and were not responding to standard anti-tuberculosis therapy and were HIV negative. Of these, 21 were suspected as NTM based on an immunochromatographic assay (ICA)-negative in culture-positive isolates result (Figure 1). The cryopreserved cultures were revived and sub-cultured on liquid (BACTEC MGIT-960) and on Lowenstein Jensen (LJ solid culture) medium using standard operating procedures (SOP) of the National Tuberculosis Elimination Programme (formerly Revised National Tuberculosis Control programme) [9,10]. These were then observed for growth rate, pigment production, and colony morphology on LJ medium (Figure 2) and initially classified based on the Runyon classification criteria [11].

HPLC and DNA sequencing

The MA extraction for HPLC (Agilent HPLC instrument) and DNA isolation for line probe assay was performed for all the cul-

Sequence analysis

The nucleotide sequence of the ITS region and *hsp65* gene of the NTM isolates were analysed using a Basic Local Alignment Search Tool (BLAST) (<http://www.ncbi.nlm.nih.gov>) (Thomas Hall, Raleigh, NC, USA). Conservative and polymorphic ITS and *hsp65* sequences of the NTM isolates were presented in a multi-alignment of the ITS and *hsp65* regions using CUSTAL-W 2.0 software (<http://genome.kribb.re.kr>). The obtained nucleotide sequences were submitted to NCBI GenBank and an accession number for ITS sequence was generated for each identified isolate [Supplementary Figure 2 (1-3)].

Results

Of the 1619 smear-positive sputum specimen received, 21 ICA-negative isolates were tested using the GenoType® Common *Mycobacteria* (CM) kit, HPLC and sequencing simultaneously. Among these, nine (45%) were identified as *Mycobacterium intracellulare*, three (15%) as *Mycobacterium gordonae*, five (25%) as *Mycobac-*

species of *Mycobacteria* (AS) kit; one (5%) was identified as *Myco-bacterium simiae* and the other was found to not be a NTM upon analysis using the GenoType® AS kit. However, one isolate were found to be invalid at the end of hybridization of GenoType®, were found as *Mycobacterium kansasii* (1; 5%) in HPLC and sequencing simultaneously (Figure 3a and 3b).

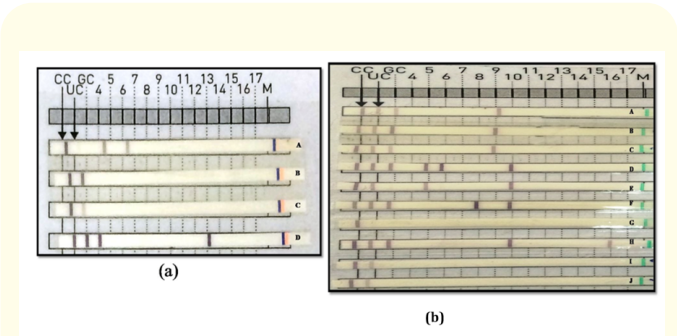

Figure 3

a. DNA strips of GenoType Mycobacterium AS kit.

b. DNA strips of GenoType Mycobacterium CM kit.

A: *M. intracellulare*; B: *M. intracellulare*; C: *M. intracellulare*; D: *M. abscessus*; E: *M. chelonae*; F: *M. gordonae*; G: GC-Negative; H: (H37RV) I: Negative control; J: Master mix control.

The prepared MA extract was subjected to HPLC (Agilent HPLC instrument) and analysis was performed using a UV detector. The obtained HPLC peaks of the NTM isolates were separated into clusters (single, double, triple, and multiple clusters) based on high and low molecular weight. Each cluster group was then identified by the number of peaks, retention times, and relative peaks heights. Of the 21 ICA-negative isolates, 20 were separated using HPLC into clusters and peaks. Among the single clusters, three (15%) were identified as *M. gordonae*, one (5%) as *M. kansasii*, previously this isolate was observed as invalid in GenoType® and one was a H37R_v as control. The double cluster included five (25%) *M. abscessus* isolates, one (5%) *M. chelonae* isolate, and 9(45%) *M. intracellulare* isolates; the triple clusters included only one (5%) *M. simiae* isolate (Figure 4a and 4b).

The results of ITS and *hsp65* genes based sequencing were identical in speciation of NTM isolates and mostly consistent with those of LPA and HPLC. One discordant result was obtained by ITS and *hsp65* gene sequencing: one species identified as *M. chelonae* by

LPA and HPLC was identified as *M. abscessus* by both ITS and *hsp65* gene sequencing. Interestingly, one isolate that could be identified neither by LPA nor by HPLC was identified using ITS and *hsp65* gene sequencing as *Nocardia cyriacigeorgica* (Table 1) and all *M. abscessus* were identified as *subsp. Bolletii*.

Discussion

Screening for *Mycobacterium tuberculosis* (MTB) using smear microscopy in patients presenting with a history suggestive of PTB is the cornerstone of tuberculosis control strategy, especially in high-burden, resource-limited countries like India. Even newer PCR-based molecular diagnostic tests such as GeneXpert MTB/RIF cannot identify NTM species, whose isolation depends on the cul-

ture and other specialized techniques. Moreover, the techniques are available only at selected centres. All these factors highlight the importance of high clinical suspicion and timely referral of patients with NTM infections for appropriate testing. NTM infections

present a unique challenge to clinicians, as their clinical and radiological presentations are similar to those of MTB, and because they show acid-fast reaction to ZN staining, which is usually the only test being performed at peripheral health centres before starting anti-tuberculosis therapy [13]. This leads to inappropriate treatment of NTM cases, sometimes even with MDR-TB regimens in view of lack of response to conventional anti-TB drugs. Since a culture-positive result for NTM is an absolute diagnostic criterion according to ATS guidelines and because treatment regimens differ according to the species, rapid species identification of NTM is essential for appropriate treatment [14,15].

The data on various techniques for NTM isolation from India are limited, with no study reporting ITS sequencing results so far. The present study was thus aimed at isolating and identifying NTM among persistently smear, culture-positive and ICA-negative isolates, where the patients infected were not responding to conventional anti-TB drugs. We used HPLC, LPA, and ITS and *hsp65* gene sequencing and compared the results of the four methods to identify the best method for NTM species identification. Our study provides pivotal information on the potentially pathogenic range of prevailing NTM species among HIV-negative sputum-positive cases from a tertiary care centre in India.

Most pathogenic NTM species are resistant to first-line anti-TB drugs and cause disease progression with persistent and often irreversible loss of lung function [2]. A vast majority of NTM cases come to light when the patient is investigated for suspected drug-resistant tuberculosis. A Chinese study revealed that about 30% of NTM isolates were from suspected MDR-TB cases, which corroborates the findings of our study [14]. Prevalence of NTM isolates can be quite high in EPTB cases, as demonstrated by a recent study from New Delhi, India, in which 12.4% of EPTB cases were actually NTM infections. The same study also identified NTM isolates in 17.4% of PTB cases who were on MDR-TB regimen [12].

The Centers for Disease Control and Prevention (CDC) proposes the use of HPLC to aid in the differentiation between tubercular and non-tubercular *Mycobacteria* [16]. In our study, of the 21 suspected NTM isolates, HPLC correctly identified 20 isolates as NTM and only one isolate was not identified; therefore, in resource-limited settings, HPLC can be a good choice for species identification. However, the turnover time (TOT) is relatively high and the requirement of special training to perform this test are the major limitations for the use of this modality [4].

The NTM isolates in our study were also tested using the GenoType® CM kit based on the principle of probe hybridization. Nine-

teen of the 21 NTM isolates were identified using the GenoType® CM kit with one invalid result. Two unidentified isolates were then tested using the GenoType® AS kit, which identified one isolate as *M. simiae*, and the other isolate was found to not be a NTM. Another study from Lucknow, India, on pulmonary specimens evaluated the performance of GenoType® *Mycobacterium* CM/AS and reported a sensitivity of 99.3% and specificity of 98.3% for NTM species identification [17]. The most common NTM species reported in the study from Lucknow was *Mycobacterium fortuitum* (20, 33.3%) among rapid growing *Mycobacteria*, and *M. intracellulare* (11, 18.3%) among the slow-growing *Mycobacteria* [16]. Another study from Mumbai, India showed that *M. abscessus* (59%) and *M. fortuitum* (41%) were the dominant species [18]. In the present study, *M. intracellulare* (43%) was found to be the predominant species, followed by *M. gordonae* (24%) and *M. abscessus* (14%).

Another study from Australia reported concordant results between LPA and HPLC for NTM identification among 119/131 clinical isolates [19]. These results were further substantiated in the present study, which showed 100% concordance between the two techniques.

One isolate that could not be detected by either LPA or HPLC was later identified as *N. cyriacigeorgica* by ITS sequencing. Nocardia infection is important and can silently present as pulmonary and extra-pulmonary diseases indistinguishable from *Mycobacterium tuberculosis* infections. *N. cyriacigeorgica* has been isolated predominantly from respiratory samples, although isolation from other sites is not infrequent and has been reported from Europe, Asia, and North America [20]. Being acid-fast, this species is often missed, and patients are subjected to erroneous treatment, which may contribute to significant morbidity and mortality. A discordant result between ITS sequencing and LPA/HPLC was found for one species, which was identified incorrectly as *M. chelonae* using HPLC and LPA and was later identified correctly as *M. abscessus* using ITS sequencing. This difference in the results obtained using the different methods could be explained by the complicated taxonomical relationship between *M. chelonae* and *M. abscessus*, both of which were earlier considered part of the *M. chelonae-abscessus* group. It was only later that *M. chelonae* was characterized as a separate species; however, clarity on this topic is still lacking in published literature [21,22].

International literature on the use of the ITS region for ribosomal gene sequencing for NTM species identification is very limited. To the best of our knowledge, this is the first study from Delhi, In-

dia, to present such data and to report concordant results between the three techniques for characterization of NTM species.

One major limitation of this study was the lack of data on co-infection of MTB and NTM, as the tests were not performed on mixed cultures. This aspect has also been infrequently reported in previous studies and could be a relevant research question for future studies [23]. Nevertheless, the findings from the present study indicate that the use of ITS (16S-23S rDNA ITS sequences) sequencing is a rapid and reliable way of NTM species identification [24].

Conclusion

The rapidity of ITS along with hsp65 genes sequencing may help in the early and accurate identification of NTM species and subspecies and will aid in initiation of appropriate treatment regimen. The rapidity, cost-effectiveness, and reliability of this technique indicates that it has potential for use as a standard of care on a larger scale.
