The prevalence, prevention, diagnosis and treatment of Dementia have been one of the essential issues for medicine and practical medicine for many years now. It requires determined researches to diagnose the disease in time and prevent complications. In this regard the work has importance not only in theory but in practice as well. It is connected with the fact that the prevalence of diseases related to memory loss is rising every day in whole world. It is encouraging that the author brings the example of his family members and relatives to show one of the types of Dementia, Alzheimer's development issues, mostly its impact on the nervous disorder and on the reducing of mental abilities.

I find these kinds of researches may be in great interest for many scientific groups and results can be published in the journal Acta Scientific Neurology, further to be used for solving purposeful pathogenic therapy problems.
